

· objective: maximize_risk_adjusted_return

A programmable capital policy engine for Solana.

Krypton converts a user's stated financial intent into an enforced, on-chain policy — then runs a multi-agent AI pipeline to execute it, with every action checked against that policy by the contract itself, not by the model's judgment.

capital → policy → agent pipeline → on-chain constraint check → non-custodial signature → repeat

Problem

Existing on-chain vaults force a choice between two bad options: a hard-coded strategy that can't adapt without a redeploy, or an off-chain "AI vault" bot whose only real check on bad behavior is its own judgment. Documented cases already show narrowly-optimized agents finding unintended loopholes when nothing independent gates their execution. Positions and reasoning are either fully public or fully custodied by an operator the user has to trust.

Solution

Krypton separates the **policy** (the user's objective, risk limits, and permissions) from the **strategy** (the ephemeral, AI-generated plan that pursues it). The policy is what's durable, auditable, and enforced on-chain. The strategy is regenerated, simulated, scored, and executed or discarded — every cycle, with no permanent strategy object anywhere in the system.

How It Works

01 — DESCRIBE

User states intent in plain language — a savings target, a growth multiple, a use as collateral. A dedicated compiler agent extracts the underlying risk envelope and checks it for feasibility before synthesizing a policy.

02 — REVIEW & DEPLOY

The synthesized policy is shown back in plain English, never silently assumed. One signature (via passkey-based, non-custodial wallet infrastructure) creates the vault; a second funds it.

03 — EXECUTE

A six-agent pipeline — research, strategy, risk, simulation, execution, monitoring — proposes and scores trades each cycle. Every proposed action is re-validated by a deterministic, on-chain Constraint Engine before it can execute, regardless of autonomy level.

04 — SIGN, NON-CUSTODIALLY

Cross-chain execution is co-signed through a threshold MPC signing network — no private key for any asset, on any chain, is ever held by Krypton, the agent, or a single party.

Who It's For

SEGMENT	WHAT THEY GET
Individual users	A personal, policy-bound vault — savings, compounding, or growth — with a strategy that adapts inside limits they set once, in plain language.
DAOs & treasuries	Programmable treasury management with policy amendments resolved by futarchy — conditional markets pricing the proposal itself — rather than low-turnout token votes.
Strategy designers (V2)	The ability to publish composable, tradable capital policies without writing smart contracts.
Institutions (V2)	Multi-signature vaults and auditable execution logs suited to compliance-conscious capital allocation.

Why Now

Autonomous agents already move meaningful on-chain volume, and the tooling for agents to sign and execute DeFi actions has matured quickly. The enforcement layer has not kept pace — most agentic vault products today have no independent check on the model's decisions. Krypton's bet is that the next phase of agentic finance is won by whoever makes the contract, not the model, the actual source of safety.

Differentiation

on-chain enforcement not model judgment — leverage, drawdown, and asset-universe limits are checked identically at every autonomy level, from advisory to fully autonomous.

non-custodial signing end to end — passkey-based wallet login and threshold MPC cross-chain execution mean no private key, anywhere in the stack, is held by a person or a server.

goal, not APY — the system optimizes toward a stated outcome inside the user's stated boundaries, and tells the user plainly when a goal and a risk limit don't actually fit together.

futarchy governance — DAO policy changes are priced by conditional markets, in the model MetaDAO has run in production on Solana, not voted on.

Go-to-Market

Launch with a small set of conservative preset policies (capital preservation, steady compounding, collateral holding) where the feasibility-checking and constraint-enforcement story is easiest to prove out, then expand into higher-variance, advisory-gated presets and DAO treasury products once the audit trail and constraint engine have a track record.

Roadmap

Beyond the initial release: composable, copyable capital policies; competing third-party execution agents with on-chain reputation; expanded cross-chain assets via the same non-custodial signing layer; institutional multi-signature vaults; tokenized vault shares.

The vault is the execution environment. The policy is the product. Krypton is not an AI hedge fund — it is a policy interpreter and a constrained, non-custodial execution layer that does exactly what it was told, and nothing else.
